Paytrace

Programmable micropayments and verifiable receipts for AI agents on Solana

The Problem & Our Solution

AI agents can't natively pay for API calls, data, or compute without subscriptions or manual billing — Paytrace fixes that on-chain.

- AI agents calling paid APIs today rely on subscriptions, API keys, or manual billing, not built for machine-to-machine payments.
- Paytrace wraps any HTTP endpoint with a pay-per-call paywall settled instantly in USDC on Solana.
- Every request generates a verifiable on-chain receipt for auditability and dispute resolution.
- No contracts, no subscriptions — agents pay exactly for what they use, per call.

How It Works

A simple SDK turns HTTP requests into pay-per-call transactions, settled on-chain with verifiable receipts.

- Agent calls an API wrapped with Paytrace SDK middleware; server responds with a 402-style payment request.
- Agent's wallet sends a USDC/SPL micropayment via Solana Pay to settle the call instantly.
- A compressed on-chain receipt (or receipt NFT) is logged proving the paid request happened.
- For long tasks, a simple escrow streams payments over time instead of one lump sum.
- Dashboard tracks each agent's spend and earnings across all connected services.

Built with

Solana, Rust, Anchor, Solana Pay, USDC/SPL Token, Node.js SDK, Compressed NFTs (state compression)

Why Now & What's Next

Agentic AI is exploding and needs native payment rails — Solana's speed and low fees make per-call micropayments viable.

- AI agents increasingly call other agents and paid APIs, but no native micropayment rail exists today.
- Solana's low fees and fast finality make per-call settlement economically practical at scale.
- Next: native integrations with AI agent frameworks like LangChain and AutoGPT-style agents.
- Next: streaming/metered payments for compute-heavy agent tasks.
- Next: a marketplace directory of pay-per-call AI services.
